

CCM SCR Secondary cooling ramp for continuous casting machine

The cooling water ramp in the continuous casting is the most important and delicate part for the correct solidification of the steel in billets, blooms, thick slabs, etc. The secondary ramp, i.e. the ensemble of sprays which spray water on the just solidified billet, needs a suitable design as well as a wide regulation versatility of the water depending on the section of the required steel ingot.

CEA designs and manufactures stands with a number of ramps variable depending on the number of zones of the cooling chambers of the continuous casting. The picture aside shows a stand with 3 cooling zones. Every zone is provided with a delivery gauger, a modulating valve, a pressure gauger and a manual gate. The gates are continuously modulating the water passing through every zone in order to grant the exact required delivery of water, while the pressure and delivery gaugers act as feedback by continuously checking the current values and immediately signalling possible troubles. The stand is entirely manufactured, electrically wired and inspected by CEA; in this way the installation turns out to be quick and reliable.

In the figure below, the inside of the electric case can be seen installed on a stand. Thanks to a remote PLC the electric connection to the rest of the plant reduces to two simple cables.

According to the needs of the customer it is possible to install a **booster** pump which elevates the line pressure of the water until the required pressure, thanks to the piloting through **inverter**. This peculiarity makes the application autonomous and independent from the rest of the plant

N Colada		Seq									
21		0									
Inicio colada		Tiempo pasado

		Inyección		20.00		100.00		100.00		20.00	

Aside, a page of a HMI CEA supervisor where it is possible to parameterise all the data relevant to the water passing through the several cooling zones. These parameters are associated to the type of steel to be produced and stored in a recipe. In this way the compilation of the parameters by the operator reduces to the simple selection of the required section.
